# GSC on Biodiversity. MAGIC

## BIODIVERSITY CONCEPTS

- First mention of the 'biological diversity' concept is attributed to **Gerbilskii and Petrunkevitch** (1955), who referred it in the context of **intraspecific in behaviour and life history**
- Biodiversity contraction was apparently first proposed by Walter Rosen in 1985.
- UNEP defines biological diversity as the **variability among living organisms** from all sources including, terrestrial, marine and other aquatic systems, and the ecological complexes of which they are part; this includes **diversity within species, between species and of ecosystems**

# GSC on Biodiversity. MAGIC

## BIODIVERSITY CONCEPTS

- As proposed by Magurran (2004), biodiversity is “the **variety and abundance** of species in a defined unit of study”
- So, for biodiversity measurement, **richness** (the variety) is important, but **relative abundance** is also a necessary component

# GSC on Biodiversity. MAGIC

## WHAT ARE WE FOCUSED ON AT UASD/IGU?

- **Focal group: woody plants**, *Cactaceae* and palms in dry, semideciduous and rainforests
- **Measurement of biodiversity**, considering both components, relative abundance and richness
- Application of **statistics and spatial statistics** to biodiversity and its relation to **geology and geomorphology**

### Getting Started:

- R is a free software environment for statistical computing and graphics. It compiles and runs on a wide variety of UNIX platforms, Windows and MacOS. To [download R](#), please choose your preferred [CRAN mirror](#).
- If you have questions about R like how to download and install the software, or what the license terms are, please read our [answers to frequently asked questions](#) before you send an email.

### News:

- **R version 3.1.0** (Spring Dance) has been released on 2014-04-10.
- **R version 3.0.3** (Warm Puppy) has been released on 2014-03-06.
- [The R Journal Vol.5/2](#) is available.
- [useR! 2013](#), took place at the University of Castilla-La Mancha, Albacete, Spain, July 10-12 2013.

# Vegan: ecological diversity

Jari Oksanen

Id: diversity-vegan.Rnw 2807 2013-12-05 11:50:52Z jarioksa processed with vegan 2.0-10 in R Under development (unstable) (2013-12-11 r64449) on December 12, 2013

## Abstract

This document explains diversity related methods in **vegan**. The methods are briefly described, and the equations used them are given often in more detail than in their help pages. The methods discussed include common diversity indices and rarefaction, families of diversity indices, species abundance models, species accumulation models and beta diversity, extrapolated richness and probability of being a member of the species pool. The document is still incomplete and does not cover all diversity methods in **vegan**.

## Contents

1	Diversity indices	1
2	Rarefaction	2
3	Taxonomic and functional diversity	3
3.1	Taxonomic diversity: average distance of traits . . . . .	3
3.2	Functional diversity: the height of trait tree . . . . .	4
4	Species abundance models	4
4.1	Fisher and Preston . . . . .	4
4.2	Ranked abundance distribution . . .	5
5	Species accumulation and beta diversity	6
5.1	Species accumulation models . . . .	6
5.2	Beta diversity . . . . .	7
6	Species pool	8
6.1	Number of unseen species . . . . .	8
6.2	Pool size from a single site . . . . .	9
6.3	Probability of pool membership . . .	10

The **vegan** package has two major components: multivariate analysis (mainly ordination), and methods for diversity analysis of ecological communities. This document gives an introduction to the latter. Ordination methods are covered in other documents. Many of the diversity functions were written by Roeland Kindt, Bob O'Hara and Péter Sölymos.

Most diversity methods assume that data are counts of individuals. The methods are used with other data types, and some people argue that biomass or cover are more adequate than counts of individuals of variable sizes. However, this document mainly uses a data set with counts: stem counts of trees on 1 ha plots in the Barro Colorado Island. The following steps make these data available for the document:

```
> library(vegan)
> data(BCI)
```

## 1 Diversity indices

Function **diversity** finds the most commonly used diversity indices (Hill, 1973):

$$H = - \sum_{i=1}^S p_i \log_b p_i \quad \text{Shannon-Weaver} \quad (1)$$

$$D_1 = 1 - \sum_{i=1}^S p_i^2 \quad \text{Simpson} \quad (2)$$

$$D_2 = \frac{1}{\sum_{i=1}^S p_i^2} \quad \text{inverse Simpson} \quad (3)$$

where  $p_i$  is the proportion of species  $i$ , and  $S$  is the number of species so that  $\sum_{i=1}^S p_i = 1$ , and  $b$  is the base of the logarithm. It is most common to use natural logarithms (and then we mark index as  $H'$ ), but  $b = 2$  has theoretical justification. The

# Package 'BiodiversityR'

January 20, 2014

Type Package

Title GUI for biodiversity, suitability and community ecology analysis

Version 2.4-1

Date 2014-01-16

Author Roeland Kindt

Maintainer Roeland Kindt <R.KINDT@CGIAR.ORG>

**Description** This package provides a GUI (Graphical User Interface, via the R-Commander) and some utility functions (often based on the vegan package) for statistical analysis of biodiversity and ecological communities, including species accumulation curves, diversity indices, Renyi profiles, GLMs for analysis of species abundance and presence-absence, distance matrices, Mantel tests, and cluster, constrained and unconstrained ordination analysis. A book on biodiversity and community ecology analysis is available for free download from the website. In 2012, methods for (ensemble) suitability modelling and mapping were expanded in the package.

**License** GPL-2

**URL** <http://www.r-project.org>,  
<http://www.worldagroforestry.org/resources/databases/tree-diversity-analysis>

**Depends** R (>= 3.0.0), tcltk

**Imports** Rcmdr (>= 1.9-4)

**Suggests** vegan (>= 1.17-12), permute, lattice, MASS, mgcv, cluster, car, RODBC, rpart, effects, multcomp, ellipse, maptree, sp, splancs, spatial, akima, nnet, dismo, raster (>= 2.0-31), rgdal, gbm, randomForest, gam, earth, mda, kernlab, e1071, tools

**NeedsCompilation** no

# GSC on Biodiversity. MAGIC

## CONCLUSSIONS

- In semideciduous forests, biodiversity measured by alpha-indices varies mainly **because of relative abundance changes**
- Richness appears to be relatively **homogeneous across different rocks substrates and landforms**

# GSC on Biodiversity. MAGIC

## CONCLUSSIONS

- **Maximum** biodiversity occurs in forests on **marlstones** and **alluvial** deposits
- **Minimum** biodiversity takes place in forests on **limestones**

# GSC on Biodiversity. MAGIC

## GEOSTATISTIC

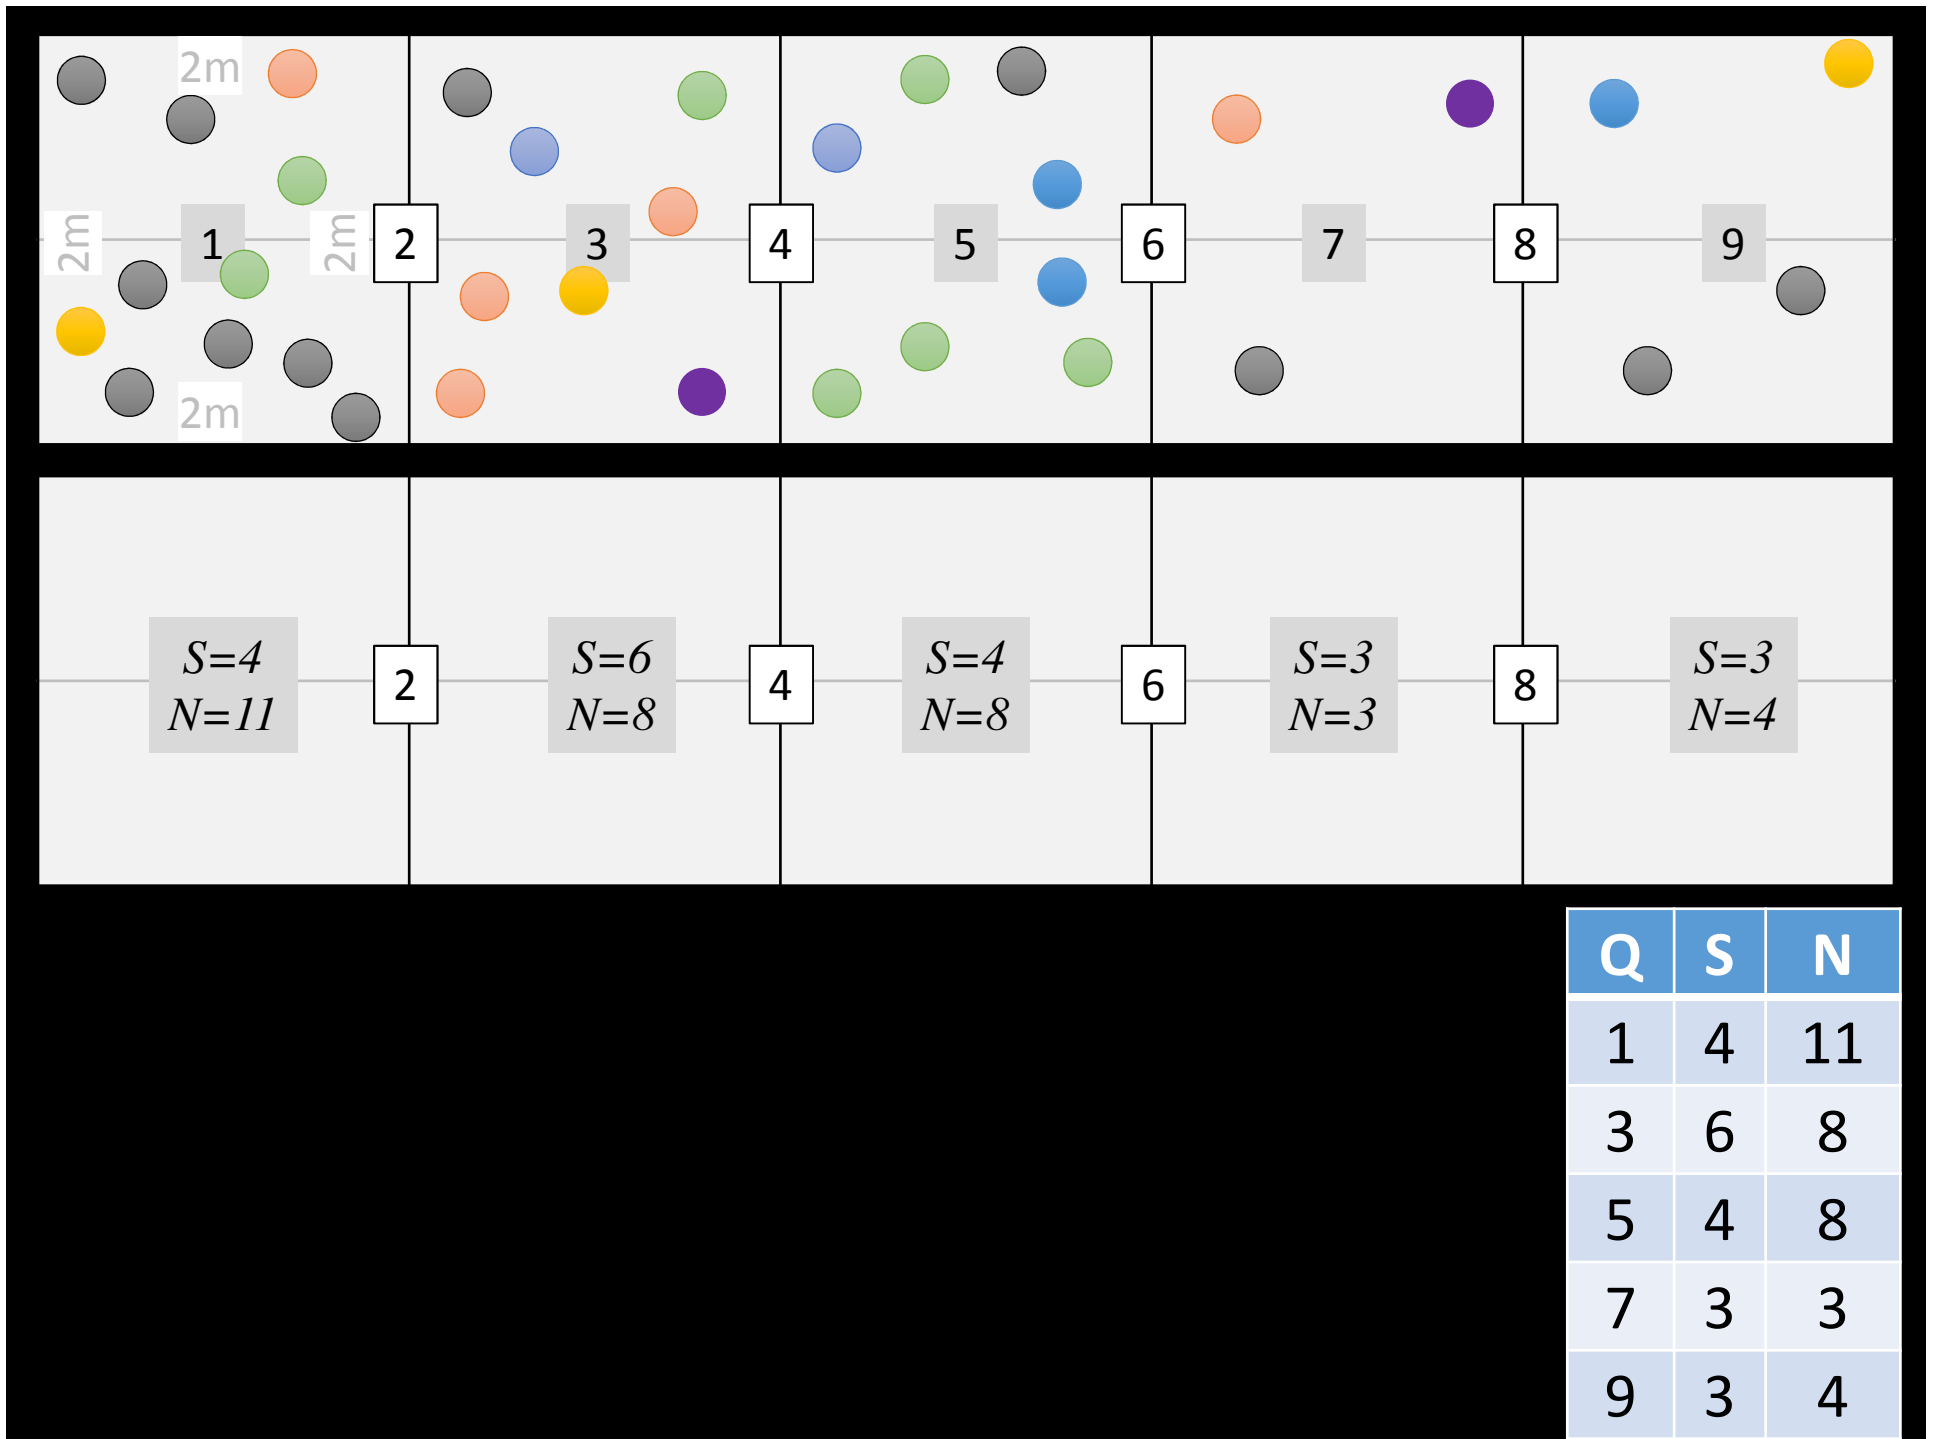

- It is statistics applied to the **study of spatio-temporal data**
- It gets support from **statistical models based on random functions** theory which models **uncertainty** related to spatial distribution

**Legend**

# Curvas de densidad de la riqueza para dos transectos parecidos, según la estadística univariante

# Curvas de densidad de la abundancia para dos transectos parecidos, según la estadística univariante

# GSC on Biodiversity. MAGIC

## CONCLUSSIONS

- At quadrat level, geostatistical analysis discovered patterns hidden to univariate statistics, and **reinforced the role of Fisher–alpha parameter as a sensitive measure of diversity**

# GSC on Biodiversity. MAGIC

## CONCLUSSIONS

- **Mature forests without livestock**, and located over **river banks/terraces**, exhibit:
  - **High spatial autocorrelation of richness and abundance**
  - Harbor great diversity measured by Fisher–alpha parameter at transect level
  - Show prevalence of singletons at quadrat level.
- These communities seems to be **local “biodiversity hotspots”**, but unfortunately they are **not included in any conservation unit** at present time.
