# Data base?

Arrangement of tables (many!), entries (many per table)

How do you get “intelligent” use of the data in the sense that you use all data connected through some common datapoints or flags?

How do you use the data “intelligent” if you want to search for as many questions as people in the earth?

# Basic instruction set for SQL query

1. **SELECT** clause. Specifies the parameters you wish to retrieve from DB.

*(what you want to get!)*

2. **FROM** clause. Specifies the database tables from where you want to extract the data.

*(from where you want to get it!)*

3. **WHERE** clause. Specifies the limitations/constraints you want to impose on the extracted data.

*(Conditions imposed on the data itself)*

# Example 1

```
SELECT objID,  
Field, ra, dec
```

(Obtains the unique objectID)

(Obtains the field number, and coordinates)

```
FROM PhotoObj
```

(From the photometric data table)

```
WHERE run=1336 and field = 11
```

(Conditions that matches our criteria)

How do you know what are the entries of the database tables?

# Schema database

<http://skyserver.sdss.org/dr14/en/help/browser/browser.aspx>

The screenshot shows the SkyServer DR14 Schema Browser interface. At the top, there's a navigation bar with links like Home, Data, Schema, Education, Astronomy, SDSS, Contact Us, Download, Site Search, Help, and History. The main content area is titled "Schema Browser" and contains a "Glossary" section with links to "Tables", "Views", "Functions", "Procedures", "Constants", and "Indices". The "Tables" link is selected. The main text explains that data is in tables, organized in columns and rows, and that views are special subsets of tables. It also mentions indices for speeding up queries. A search bar is present with a "Go" button. The bottom of the page has a footer with a copyright notice and a link to the SDSS website.

## Schema Browser

Glossary  
Algorithms

Search for

- ☒ Tables
- ☐ Views
- ☐ Functions
- ☐ Procedures
- ☐ Constants
- ☐ Indices

The data in the database is contained in **Tables**, organized in columns and rows. We have defined **Views** over the tables. These represent special subsets of the original table.

Most of the tables also have one or more **Indices** defined on them to speed up queries on them. Please see the **Archive Intro** Help page for more information on the types of indices.

**Functions** and stored **Procedures** take a number of parameters, and execute a previously defined sequence of commands. Usually, their names are prefixed by *f* or *sp*, like in *fPhotoStatus* or *spGetFiberList*.

The table **SDSSConstants** contains most of the parameters relevant to the SDSS. Their values can be displayed by clicking on the link in the left hand panel.

The table **DataConstants** contains most of the bit-flags and enumerated quantities relevant to the SDSS. Their values can be displayed by clicking on the link in the left hand panel. There are several access functions to make interpretations and the "back and forth conversions easier. They are displayed when you look" at the individual enumerated fields."

Tables → Views → Functions and procedures → Constants

# Imposing no conditions to the query

```
SELECT ra, dec  
FROM Galaxy
```

Take all RA and DEC coordinates for all galaxies  
in the Galaxy VIEW

# Rich syntax for SQL

*(sometimes source of mistakes)*

```
SELECT TOP 100 u,g,r,i,z  
FROM Galaxy  
WHERE r<12 and r>0
```

```
SELECT TOP 100 u,g,r,i,z  
FROM Galaxy  
WHERE r BETWEEN 0 AND 12
```

```
select top 100 u,g,r,i,z  
From Galaxy  
WHEre r<12 and r>0
```

They all do the  
same query!

- ✓ Case insensitive
- ✓ Various forms for execution of comparison

# Considering invalid flags-values

```
SELECT ra, dec, u, err_u  
FROM PhotoObj  
WHERE ra BETWEEN 180 AND 181  
AND dec BETWEEN -0.5 AND 0.5  
AND u BETWEEN -9999 AND 20.0  
AND err_u BETWEEN -1000 AND 0.1
```

What is the meaning of this query?

# Using data from two tables

```
SELECT s.psfMag_g  
FROM Star s, Field f
```

```
WHERE s.fieldID = f.fieldID
```

```
and s.psfMag_g < 20
```

```
and f.pspStatus = 2
```

Note that now we have  
an “alias” for each table

And so we use it

# What is the meaning of this query?

```
SELECT p.objID, f.field, g.run
```

```
FROM PhotoObj p, Field f, Segment g
```

```
WHERE f.fieldid = p.fieldid  
and f.segmentid = g.segmentid
```

Conditions are used to join them together

Data is taken from  
three different tables

## Or three tables!

```
Select  plateX.plate, plateX.mjd, specObj.fiberID,  
PhotoObj.modelMag_u, PhotoObj.modelMag_g,  
PhotoObj.modelMag_r, PhotoObj.modelMag_i, PhotoObj.modelMag_z,  
PhotoObj.ra, PhotoObj.dec, specObj.z, PhotoObj.ObjID  
from
```

```
    photoObj, specObj, plateX
```

```
where
```

```
    specObj.bestObjid = PhotoObj.ObjID
```

```
    and plateX.plateID = specObj.plateID
```

```
    and class = 'qso'
```

```
    and specObj.zWarning = 0
```

```
    and specobj.z between 0.3 and 0.4
```

# Outer joins

*What if you are not rigorous about the data from the query?*

Non inclusive query      →    use outer joins

```
Select P.objID, P.ra, P.dec, S.SpecObjId,S.ra, S.dec  
From PhotoObj as P left outer join SpecObjAll as S on  
P.objID = s.BestObjID
```

All data from **P is taken**, missing data from s is filled with NULL

# Calling functions from the DB

```
select top 100 z, dered_u, dbo.fCosmoAbsMag(dered_u, z,  
DEFAULT,DEFAULT,DEFAULT,DEFAULT,DEFAULT)
```

```
from SpecPhoto
```

```
where z > 0 and zWarning=0
```

## Your SQL command was:

```
select top 100 z, dered_u, dbo.fCosmoAbsMag(dered_u, z, DEFAULT,DEFAULT,DEFAULT,DEFAULT,DEFAULT)  
from SpecPhoto  
where z > 0 and zwarning = 0
```

## Your query output (max 500,000 rows):

z	dered_u	Column1
0.5379699	23.57166	-18.8945730913955
0.4058664	17.83873	-23.893199709389

## FUNCTION **fCosmoAbsMag**

Returns the absolute magnitude of a galaxy at a particular redshift.

Parameters:

Go

@m float: aparent magnitude of the object

- @z float: redshift
- @OmegaM float: matter density. If set as DEFAULT, then 0.27891507
- @OmegaL float: dark energy density. If set as DEFAULT, then 0.721
- @OmegaR float: radiation density. If set as DEFAULT, then 8.493e-5
- @omega0 float: dark energy state equation. If set as DEFAULT, then -1
- @h\_0 float: (hubble constant[Km/s/Mpc])/(100[Km/s/Mpc]). If set as DEFAULT, then 0.701

Reference: [http://lambda.gsfc.nasa.gov/product/map/dr3/pub\\_papers/fiveyear/cosmology/wmap\\_5yr\\_cosmo.pdf](http://lambda.gsfc.nasa.gov/product/map/dr3/pub_papers/fiveyear/cosmology/wmap_5yr_cosmo.pdf)

- returns AbsMag: absolute magnitude

```
select dbo.fCosmoAbsMag(17.5,0.1,0.27891507,0.721,8.493e-5,-1,0.701);select  
dbo.fCosmoAbsMag(17.5,0.1,DEFAULT,DEFAULT,DEFAULT,DEFAULT,DEFAULT)
```

return -20.8155123821697 and -20.8155123821697

see also fCosmoDistanceModulus

### Input and output parameters

name	type	length	inout	pnum
@m	float	8	input	1
@z	float	8	input	2
@OmegaM	float	8	input	3
@OmegaL	float	8	input	4
@OmegaR	float	8	input	5
@omega0	float	8	input	6
@h_0	float	8	input	7
	float	8	output	0

Lets get the objects from the database at a given distance from a point with coordinates RA and DEC

```
Select p.ObjID, p.ra, p.dec, p.u, p.g, p.r, p.i, p.z
```

```
From photoObj p, dbo.fGetNearbyObjEq(140,20,5) n
```

```
Where p.objID = n.objID AND p.type = 3
```

`dbo.fGetNearbyObjEq(140, 20, 5)`

RA

DEC

Radius (arcmin)

This function returns a table!  
You can query it inside your query

## SQL Tutorial

NOTE: This is a step-by-step tutorial for those new to SQL. If you already know some SQL and want a more in-depth introduction to how SQL applies to SkyServer, see [Using SQL with SkyServer](#).

Another great way to learn SQL is to modify and submit queries that other people have already written. To jump right in to modifying queries written by scientists, see the [Sample SQL Queries](#).

## Searching for Data: A Tutorial

Did you know that you can search through SkyServer's database for only the objects you are interested in? For example, you might want to find all the bright blue galaxies for which we have obtained spectra. Looking through all 14 million objects with the Navigation tool could take years. But using [the right search](#), you could find all the bright blue galaxies with spectra in seconds!

 millimil (context)

Streaming queries return unlimited number of rows in CSV format and are cancelled after 30 seconds.  
Browser queries return maximum of 1000 rows in HTML format and are cancelled after 30 seconds.

There is a [partial mirror](http://galaxy-catalogue.dur.ac.uk:8080/Millennium/) of this database in Durham at <http://galaxy-catalogue.dur.ac.uk:8080/Millennium/> .  
The Durham database does not contain all the latest L-Galaxies models but does contain more recent GALFORM models.

Help

Maximum number of rows to return to the query form:

10

**Demo queries:** click a button and the query will show in the query window.

Holding the mouse over the button will give a short explanation of the goal of the query. These queries are described in some more c

```
SELECT TOP 1000  
g.run, f.field, p.objID  
FROM photoObj p, fieldf, segment g  
WHERE f.fieldid= p.fieldid  
and f.segmentid = g.segmentid  
and f.psfWidth_r > 1.2  
and p.colc > 400.0
```

When using table valued functions, you must do the join explicitly (rather than using "="). To do this, we use the syntax  
SELECT quantities

FROM table1

JOIN table2 on table1.quantity =table2.quantity

WHERE constraints
